1.0 INTRODUCTION

1.1 BACKGROUND

Escambia County (County) contracted with Hatch Mott MacDonald (HMM) to prepare a Stormwater Management Master Plan for unincorporated Escambia County. During Phase 1 of the effort, forty-one major drainage basins were identified. The Warrington Basin is one of these basins selected to be studied in more detail and have a Stormwater Management Master Plan developed for the basin.

The Warrington Basin is a 8254-acre (12.90 square mile) watershed located in the south western portion of Escambia County (see Figure 1-1). The majority of the basins drain to Bayou Chico which outfalls into Pensacola Bay. A large portion of the primary drainage components of the basins consists of natural tributaries that drain into Jones Swamp Creek and Jackson Creek. Jones Swamp Creek is located in the southwest portion of the drainage basin south of Highway 98 and outfalls into Bayou Chico east of Old Corry Field Road. Jackson Creek is located near the center of the drainage basin running north to south and turns to the east just north of Corry Field, which also outfalls into the upper portions of Bayou Chico north of Navy Boulevard known as Bell's Head Branch. The overall basin has been divided into 11 areas labeled A thru K. These areas are referred to as Branches and can be seen on the overall drainage map (Attachment A).

Branch A of the system, a 2,259-acre watershed, consists of the Jones Swamp channel that discharges into Bayou Chico. Areas within this watershed are comprised of the storm sewer on Corry Field, portions of Navy Boulevard, and Highway 98, all of which discharge to Jones Swamp. Branch B, a 748-acre watershed, located in the area between Highway 98 and Lillian Highway. This system is primarily comprised of several small storm sewer systems that discharge to Lake Charlene. Other portions of the watershed are comprised by overland flow through a system of culverts and ridges, which connect the sub-basin areas together. The pop-off for Lake Charlene is through a sluice gate to an open channel system where it discharges through a large pipe system to Jones Swamp Creek. Branch C, a 677-acre watershed, is comprised primarily of overland flow through a system of open ditches, swales, and culverts along Fairfield Drive and areas south of

Highway 98. This ditch system also discharges to Jones Swamp Creek. Branch D, a 362-acre watershed, extends from Old Corry Field Road to Fleet Road on Barrancas Avenue. This system also includes the Star Lake Subdivision, which is in the southern portion of the watershed. The northern portion of the watershed consists primarily of a storm sewer that runs along Barrancas Avenue and discharges to Star Lake. The southern portion of the watershed comprises primarily of overland flow connected by a system of low areas in natural ridges. The portion also discharges to Star Lake. Branch E, a 140-acre watershed, consists of the storm sewer on East Barrancas Avenue. This branch of the storm sewer is located between Fleet Road and the old Bayou Chico Bridge and discharges directly to Bayou Chico. Branch F, a 336-acre watershed, is located between Navy Blvd and Barrancas Avenue. This watershed is separated by Bayou Chico. Both portions of this system are comprised primarily of overland flow through a system of culverts, which connect the sub-basin areas together. This system discharges to Bayou Chico. Branch G, a 334-acre watershed, does not have an existing storm sewer system. This area extends from Old Corry Field Rd to 'W' Street. The sub-basin areas in this branch are connected by a system of low areas in natural ridges. Branch H, a 561-acre watershed, is located from Corry Field to its outfall at Bayou Chico. This system is comprised primarily of overland flow through a system open channels, which connect the sub-basin areas together. Branch I, a 564-acred watershed, is located on New Warrington Road and extends from Highway 98 to Mobile Highway. This watershed contains a storm sewer system on New Warrington Road and a portion of Mobile Highway. This system discharges to Jackson Creek. Branch J, a 113-acre watershed, is located west of New Warrington Road from State Street to West Gregory Street. The lower portion of this system is comprised of open ditches and the upper portion of this system is a storm sewer system that extends from State Street to West Jackson Street. This system discharges to Jackson Creek. Branch K, a 586-acre watershed, extends from Lillian Highway to Prieto Drive. This system is comprised primarily of overland flow through a system of open channels, which connect the sub-basin areas together. This system also discharges to Jackson Creek.

Land surface elevations in the basins range from highs of 95 feet NGVD in the northern end to lows of 0 feet NGVD at the outfall. The Soil Conservation Service (SCS) hydrologic soil groups within the basin are approximately 83 percent group A, 2 percent group B, and 15 percent group D. No group C soils are present in the basin. The predominate Group A soils, which have excellent

infiltration rates, give the overall basin good percolation capabilities. The Warrington Basin contains two stream flow gauges. Stream gauge 87 is located on Jones Swamp Creek at Navy Boulevard just south of Highway 98, and stream gauge 89 is located on Jackson Creek east of Old Corry Field Road and south of Danbury Circle. These gauges were operated by the Northwest Florida Water Management District (NWFWMD) until the early 1990's. Land use throughout the basin is broken down as follows: 16.6 percent public, 47.6 percent residential, 18.0 percent commercial, 4.0 percent industrial, and 13.8 percent agricultural. The basin is essentially considered completely built-out. The existing development density for the basin is 2.10 Equivalent Residential Units (ERU's) per acre, which is the fourth highest of the 41 basins in Escambia County. The basin is not classified as one of Escambia County's projected high growth basins. The population increase for the basin from the year 2000 to the year 2015 is projected to be 15.2 percent.

1.2 OBJECTIVES

The purpose of the Stormwater Management Master Plan for the Warrington Basin is to address flooding and stormwater quality problems within the basin and prevent future flooding and stormwater quality problems from occurring. The analysis of this plan is confined to the primary drainage system only. The primary drainage system consists of streams, open ditches, lakes, and ponds draining an area of 50 acres or more and closed conveyances of equivalent diameter 36 inches or more. In areas of known flooding problems, smaller conveyances were modeled. This study involved the development of a hydrologic and hydraulic model of the primary drainage system. The results from this model show the extent of flooding at critical points along the primary drainage system for the "as is" condition assuming the system is maintained. The model will also show the extent of flooding at critical points, if upgrades to the primary system are employed in order to achieve an acceptable degree of flooding. Furthermore, the model can be used to show the flooding impacts that new developments will have on downstream areas. With this model, the County can recommend priorities for drainage improvement projects, determine existing levels of service standards, and provide design guidance to area engineers regarding tailwater conditions of the primary system.

2.0 HYDROLOGIC / HYDRAULIC MODEL DEVELOPMENT

2.1 MODELING SOFTWARE

The Warrington drainage basin was modeled using the Advanced Interconnected Channel and Pond Routing (ADICPR) Model, Version 3.0 (Windows) marketed by Streamline Technologies, Inc. ADICPR is used to model hydrologic conditions to generate a runoff hydrograph from a drainage sub-basin and to hydrodynamically route stormwater flow through the stormwater conveyance system. As such, it combines the hydrologic and hydraulic modeling functions into one model.

ADICPR is a stormwater management analysis and design tool. There are routines to input and edit data, compare runoff hydrographs and flood route hydrographs through complex pond and conveyance systems. Time-variable tailwater conditions, flow reversals, and looped hydraulic networks are included in its solution algorithm. ADICPR is able to analyze an extensive array of hydraulic structures including culverts under all flow regimes. Results can be reviewed and analyzed with an extensive data base retrieval system. A variety of tabular and graphical reports can be easily generated for review by the user or for submittal to reviewing agencies.

2.2 DRAINAGE FACILITY INVENTORY, MAPPING AND DATA COLLECTION

Aerial and topographic information used for the model was provided by Escambia County's Geographic Information System (GIS) Division. The aerial photograph maps have topography with one-foot contour intervals, which provide a level of detail necessary to delineate the drainage patterns within the flat areas of the basin. These maps are provided as attachments in the back of this report.

Primary drainage facilities and sub-basin delineations are shown on the aerial maps and these maps represent the existing condition as of August 2005. Attachment A shows the Warrington Basin drainage map. HMM conducted extensive field research by driving and walking the basin, while recording drainage patterns, mapping drainage facilities, measuring facility dimensions, and inspecting the condition of the drainage facilities. An equally extensive amount of effort was expended in researching and collecting construction plans for roadways and developments

throughout the basin. The source of information for these plans was the County and FDOT. The construction plans allowed for explicit modeling of the roadways and developments and the retention/detention ponds that collect and control their discharge. All of this effort was required to develop the level of detail necessary to define the hydrologic and hydraulic conditions of the basin.

The development of the Warrington Basin model also required a tremendous amount of surveying effort. In order for the model to be a reasonably accurate representation of the actual hydrologic and hydraulic features of the basin, surveying information was required for drainage structures (pipes, culverts, storm sewers, and bridges), ponds (retention/detention ponds, natural ponds, and lakes), and channel cross-sections. Information obtained for drainage structures included type and shape of structure, upstream and downstream invert elevations, length of structure, and roadway profile elevations above the structure. Pond information included water surface elevation, surface area, berm profile elevations, size, type, and invert elevations of any control structures. Open channels and ditches located in the basin required cross-section data, length of the channel or ditch, and upstream and downstream invert elevations. Table 2-1 at the end of this chapter summarizes the existing drainage system.

2.3 HYDROLOGIC DATA

Hydrologic modeling with the ADICPR model was performed utilizing the Soil Conservation Service (SCS) Unit Hydrograph method as a means of computing stormwater runoff rates into the conveyance system. The SCS Unit Hydrograph method requires the following information:

(1) A non-dimensional unit hydrograph with associated peaking factor.
(2) Drainage area.
(3) Percentage of directly connected impervious areas.
(4) Runoff curve numbers for all areas, which are not considered to be directly, connected impervious areas.
(5) Times-of-concentration.

Whenever the SCS Unit Hydrograph method is selected, a non-dimensional unit hydrograph must be specified. The unit hydrograph and peaking factor directly affect the peak runoff rate. The proper selection of a unit hydrograph depends on the geographical area and local conditions. Flat

areas have lower peaking factors and steep areas have higher peaking factors. ADICPR has three standard curvilinear unit hydrograph files with corresponding peaking factors of 256, 323, and 484. ADICPR also allows the unit hydrograph and peaking factors to vary between sub-basins. For the Warrington Basin, a peaking factor of 256 was used for sub-basins with an average overland slope of less than 0.5 percent, a peaking factor of 323 was used for sub-basins with an average overland slope between 0.5 and 1.5 percent, and a peaking factor of 484 was used for sub-basins with an average overland slope greater than 1.5 percent.

To develop the Warrington Basin model, the basin was divided into 326 separate sub-basins, which are shown on the drainage map (Attachment A). These sub-basins were delineated from the County's aerial photograph maps with one-foot contour interval topography and by field reconnaissance of the basin.

Directly connected impervious area (DCIA) is defined as impervious area that is connected directly to the sub-basin outlet point (i.e. node) without flowing over any pervious surfaces. In the Warrington Basin, all curb and gutter roadways that convey runoff directly to inlets were included as DCIA.

A spreadsheet using the SCS Technical Release 55 (TR-55) procedures was used to calculate the runoff curve numbers (CN) and the time-of-concentrations (TC) for each individual drainage sub-basin. A copy of this spreadsheet is included in Appendix A. The runoff curve number (CN) is a function of a number of factors including hydrologic soil group, cover type, land use, treatment, hydrologic condition, and antecedent moisture condition. Each of the sub-basins was divided into land uses and then the land uses were further divided into soil types. From this area-weighting procedure, a composite CN number was then calculated. This method is detailed in the SCS TR-55 Manual, Urban Hydrology for Small Watersheds. Table 2-2 shows the land uses each of the Warrington basins were divided into. It also shows the CN numbers used to compute the composite CN numbers for each basin.

The sub-basin time-of-concentration (TC) represents the amount of time it takes for a particle of water to travel from the hydrologically most distant point in the drainage sub-basin to its outlet (node). The spreadsheet (Appendix A) based on the TR-55 method was used to calculate the TC's

for each of the Warrington model sub-basins. In this method, the TC is computed by summing all the travel times for consecutive components of the drainage conveyance system. Flow times are computed for sheet flow, shallow concentrated flow, open channel flow, and pipe flow as a function of slope and the type of flow path.

The hydrologic data input to the ADICPR model for the Warrington Basin is summarized in Table 2-3. Sub-basins range in size from 1.1 acres to 127.2 acres with an average of approximately 20.4 acres. Runoff curve numbers range from 56 to 98 and time-of-concentrations vary from 3 minutes to 336 minutes.

2.4 HYDRAULIC DATA

ADICPR hydrodynamically simulates unsteady flow in a drainage system that consists of open channels, ponds, culverts, and a variety of control structures. The model takes sub-basin runoff hydrographs and routes them through a series of reaches. The model can also accommodate time-varying boundary conditions. ADICPR works on a node-reach concept. This is a simple concept, which involves identifying locations in the drainage system where water surface elevations are to be calculated. Each of these locations is considered a node. Nodes are connected together with conveyance elements (channels, culverts, weirs, etc.) called reaches. Discharge rates are computed for each reach. The entire system of nodes and reaches forms the nodal network and serves as the computational framework for ADICPR.

The ADICPR model for the Warrington Basin was developed with the intention of explicitly modeling the primary system. After studying the system closer, it was determined that some portions of the secondary system would have to be modeled in order to more accurately distribute the runoff hydrographs into the primary system and define low lying flood prone areas. Figure 2-1 at the end of this chapter is a model schematic of the drainage network for the existing conditions. A more detailed schematic of the drainage network is shown on the drainage map (Attachment A). Each of the 326 sub-basins was assigned a discharge location (node) and flows were routed through the drainage network from that point on. As shown in the model schematic, the ADICPR model of the Warrington Basin consists of 393 nodes connected by 437 reaches.

Physical dimensions and elevations of the drainage system were obtained from field surveys, aerial photographs with contours, and construction plans as discussed earlier. Roughness coefficient (Manning's n) values of 0.012 and 0.024 are used for reinforced concrete pipe (RCP) and corrugated metal pipe (CMP) culverts, respectively. Channel roughness coefficients range from 0.050 to 0.060 for defined channels and from 0.080 to 0.100 for out of bank flood plains. Weir coefficients of 2.8 are used for both natural berms and roadway over-toppings. Culvert entrance loss coefficients range from 0.2 for pipes projecting into inlets to 0.7 for mitered end sections. Table 2-4 summarizes the ADICPR model network for the existing drainage facilities.

Also included in the model are retention/detention ponds, which serve in one capacity or another as storage reservoirs for surface water runoff. Some of these ponds have a very large storage capacity, and they serve to greatly attenuate peak flows within the basin. ADICPR simulates these ponds as nodes with elevation-area relationships defining the storage volume. Rating curves are used to give these ponds percolation rates. Percolation rates were taken from the Escambia County Soils Survey published by the United States Department of Agriculture, Soil Conservation Service based on the particular types of soils present. If a range of rates are listed, the most conservative value was used.

2.5 TAILWATER CONDITIONS

There are four discrete watersheds that make up the Warrington Basin, two of which outfall to the same water body. These two watersheds discharge to Bayou Chico, but in two different locations, Upper Bayou Chico, known as Bell's Head Branch, (Jackson Creek) and the central area of Bayou Chico (Jones Swamp Creek). Both of these systems discharge through an open ditch system that runs through Jones Swamp and Jackson Creek. The third discrete watershed discharges directly into Pensacola Bay and the fourth to Star Lake. These tailwater conditions are tidally influenced and the discharges are submerged. Since the tailwater fluctuates with the elevations of Bayou Chico, Pensacola Bay, and Star Lake, this will have some effects on the immediate upstream stages of the system. An initial stage of 0.00 was used for all three water bodies. It should be noted that there is a potential for storm surges from tropical storms and hurricanes to produce higher initial tailwater conditions at the beginning of a storm resulting in higher flood stages in all areas upstream of the outfall.

2.6 MODEL CALIBRATION

In order to validate the model, historical flood stage records and stream flow data must be used to determine which model parameters can be reasonably adjusted so that the model results are in reasonable agreement with measured flow and stage data. The Warrington Drainage Basin contains two stream gages. The stream gages are located on Jones Swamp Creek (S-87) just downstream of Navy Boulevard and on Jackson Creek (S-89) east of Old Corry Field Road. These gauges were operated by NWFWMD until the 1990's. No data exist after this period. Stream flow data from the gages were used for comparison of model hydrologic features such as hydrograph volumes, timing, shapes, and peak flows. Flood stage data from the gages was used for comparison of hydrologic features such as stream flow responses to storm hydrographs and hydraulic parameters such as channel roughness coefficients. Two historic rainfall events were used as model calibration storms. These events were the June 8, 1989 storm and the March 15, 1990 storm and they were selected based on their intensity and the amount of available stream flow and rainfall data. The June 8, 1989 storm had an average rainfall volume of 6.35 inches and an average duration of 29 hours. The March 15, 1990 storm had an average rainfall volume of 6.83 inches and an average duration of 35 hours.

The model simulated both storm events. It was the intent of the calibration to match the peak flows, the timing, the volumes and the overall hydrograph shapes of both simulations as closely as possible to the calibration storms. To achieve this calibration, the new CN numbers needed to be adjusted. Since most of the run-off curve numbers are on the conservative side, they tend to produce more runoff than occurs during the actual storm event. The CN numbers were reduced by an average of about 19 percent on all of the sub-basins. This achieved a practical model calibration to both storm events to validate the model and these calibration adjustments of the Warrington Basin model provide a reasonable depiction of actual conditions. Figure 2-2 shows the measured stream data verses the simulated data for both stream gages and calibration storm events.

TABLE 2-2 (Con't)

TABLE 2-2

RUNOFF CURVE NUMBERS (CN) BASED ON SOIL CONSERVATION SERVICE (SCS) VALUES

COVER TYPE & HYDROLOGIC CONDITION	HYDROLOGIC SOIL GROUPS			
	A	B	C	D
PASTURE/GRASSLANDS	68	79	86	89
DENSE WOODS	36	60	73	79
ORCHARD TYPE WOODS	56	73	82	86
OPEN SPACE (Lawns, Parks, Golf Courses, Cemeteries, etc.)				
POOR HYDROLOGIC CONDITION (Grass Cover < 50%)	68	79	86	89
FAIR HYDROLOGIC CONDITION (Grass Cover 50% -75%)	49	69	79	84
GOOD HYDROLOGIC CONDITION (Grass Cover > 75%)	39	61	74	80
RESIDENTIAL DISTRICTS BY AVERAGE LOT SIZE				
1/4 ACRE (38% Avg. Impervious Area)	61	75	83	87
1/2 ACRE (25% Avg. Impervious Area)	54	70	80	85
1 ACRE (20% Avg. Impervious Area)	51	68	79	84
2 ACRE(12% Avg. Impervious Area)	46	65	77	82
COMMERCIAL & BUSINESS (85% Avg. Impervious Area)	89	92	94	95
INDUSTRIAL (72% Avg. Impervious Area)	81	88	91	93
STREETS & ROADS	98	98	98	98

All Group numbers have been adjusted for the calibration process. See Section 2.6

3.0 EXISTING CONDITIONS FLOODING ASSESSMENT

3.1 DESIGN STORM EVENTS

The design storm events identified in the scope of services and chosen for simulation by the model were the 3-year, 25-year, and 100-year frequency, critical duration rainfall events. These three storm events provide a basin analysis for an above average storm condition (3-year), the County's design standard event (25-year), and a severe storm condition (100-year) likely to occur only during a hurricane or other exceptional rainfall occurrence. It should be noted that the 100-year storm event has a 1 percent chance of occurring in any given year. Hyetographs were developed using the Florida Department of Transportation (FDOT) Rainfall Intensity-Duration-Frequency (IDF) Curves for Zone 1.

To determine the critical duration for the Warrington Model, the 100-year storm event was simulated with durations of 1, 2, 4, 8, 24, 72, 168, and 240 hours. Each node was evaluated based on the maximum stage reached for each of these durations. Table 3-1 at the end of this chapter shows the results for this critical duration analysis. Based on these results, the 8-hour duration is the critical duration for the majority of the basin. The rainfall volumes used for each of the 8-hour duration storms are 5.1 inches for the 3-year, 7.4 inches for the 25-year, and 9.4 inches for the 100-year storm events.

3.2 FLOOD DATA COMPILATION:

To provide an accurate assessment of flooding conditions within the Warrington Basin, pertinent information was compiled which included review of previous studies, interviews with county staff and residents, review of Escambia County Road Operations Department records related to drainage, field reconnaissance, and citizen survey questionnaires. Two previous studies reviewed were the Preliminary Stormwater Management Assessment prepared in March 1991 and the Escambia County Stormwater Master Plan Needs Assessment prepared in November 1994 both by HMM (then Carlan Consulting Group) and Camp Dresser McKee (CDM). These two studies provided relevant information to existing flooding conditions. All work orders and drainage complaints within the Warrington Basin were obtained from the Road Operations Department and reviewed to

further evaluate the extent of flooding within the study area. All work orders outside the primary drainage system were field inspected to determine if the problem was a maintenance issue or an inadequate drainage system.

In order to incorporate the concerns of the citizens and to provide a historical reference of the flooding problems, questionnaires were mailed to approximately 7100 residents who lived, owned a business, or owned property within the Warrington Basin. A response of 6 percent was received from the questionnaires. Even with the low response rate, a considerable amount of information was obtained. It appeared that the residents within the flood prone areas were more inclined to respond than the ones who had no flooding problems. Results of these questionnaires are summarized in Table 3-2 and the questionnaire form is included as Appendix C. Figure 3-1 is a map that shows the locations of reported flooding problems from the questionnaires. HMM conducted telephone interviews and scheduled field meetings with some of the residents who reported the most severe flooding conditions.

3.3 ADICPR MODEL RESULTS

Table 3-3 shows the model results for the Warrington Basin for the three design storm events. The warning stage is set to the inlet top elevations for the storm sewer systems, top of bank or ditch elevations for channels and roadside ditches or swales and to the top of berm or top of bank elevations for all ponds. Any elevation in excess of this stage indicates a flooding condition. It should be noted, however, that a flooding condition does not necessarily mean a flooding problem. Flood conditions are as follows: 0 means no flooding conditions, 1 means a flooding condition during the 100-year storm event, 2 means a flooding condition during the 25-year storm event, and 3 means a flooding condition during the 3-year storm event. Also, Table 3-4 illustrates the height and duration of time the flood stage is above the warning stage for all nodes with flooding conditions. The depth varies from zero to the maximum and back to zero throughout the duration of the flooding condition.

From the model results, profiles were developed that show all nodes, warning stages, and the flood stages for the three design storm events. These profiles are shown in Figure 3-2 at the end of this chapter and are a valuable tool for evaluating flooding conditions to determine if there is a flooding

problem. The profiles show which problem areas are due to tailwater conditions and which problem areas are due to under sized conveyances. Furthermore, tailwater conditions can be traced downstream to their source. The model results were also used to develop 100-year flood plain maps. It should be noted that these flood plain maps are not the same as the Federal Emergency Management Agency (FEMA) flood plain maps. These maps show the 100-year flood plain based on the ADICPR Model results and are included as Attachment B.

3.4 FLOODING EVALUATION:

All model results were compared with the known flooding problems, the citizen questionnaires and the field investigations. Table 3-3 illustrates all areas with flooding conditions and Table 3-4 shows the depth and duration of these conditions. As noted earlier, a flooding condition does not necessarily mean a flooding problem. Flooding conditions are considered problems in areas with streets and yards flooding for an extended period during a 25-year storm event and any area where a home or business floods during a 100-year storm event. The following summarizes the flooding problems by delineating the branches and zones for the overall Warrington Basin.

Branch A:

The majority of the open ditch system running though Jones swamp has adequate capacity for the critical duration of the 25-year storm. Within Branch A, the majority of the stormwater system has sufficient capacity to convey the flow to the pop off at Bayou Chico. To determine whether or not these areas have flooding problems, the surrounding elevations and areas were reviewed. There is one area in this branch that is considered to have some minor flooding conditions in the 100-year critical storm event. This area is located in the perimeter of the Corry Field Naval Base. Since this area is not in the county right-of-way, no improvements are presented. In addition, there are two areas that are considered to have significant flooding conditions. One of these areas is located west of Fairfield Drive along Hickory Street. The model shows this area flooding during the 100-year critical storm event. The other area is located North of Patton Drive just west of Navy Boulevard. The flooding conditions in this area are associated with the 3-year critical storm event and show significant flooding to residences and businesses. Even though the model shows flooding conditions in these two areas, both areas are located in the flood plain, therefore; no improvements

are presented because there is very little that can be done to the actual Swamp to prevent these flooding conditions.

Branch B:

The primary drainage system for Branch B is a storm sewer system in the Lake Charlene Subdivision and extends north to Myrtle Hill Circle. This storm sewer system conveys the stormwater to Lake Charlene and then discharges via a dam and weir system, this system then pops-off to Jones Swamp. There are several areas that the model shows some minor flooding conditions during the 100-year critical storm event. The majority of the areas are located near the edge of the lake and canal that are associated with Lake Charlene. In addition, there are an extensive number of areas that show flooding during the 25 and 3-year critical storm events. These areas are located along Kitty Hawk Drive, Lake Joanne Drive, 61st Avenue, Lake Charlene Drive, Myrtle Hill Circle, and Penton Street, along with several other side streets. The flooding conditions in these areas are extensive and encroach citizen's private residence. In this basin alone, there are 57 sub-basins and of these 57 sub-basins, 37 are showing some type of flooding condition. It is apparent from the model that Lake Charlene is taking on too much stormwater, and the amount of stormwater needs to be drastically reduced, along with improving the existing systems that are in place.

Branch C:

The majority of Branch C is located along Fairfield Drive between Highway 98 and Baysprings Drive. The primary drainage system along Fairfield Drive is an open ditch and culvert system. There is also a secondary system along Highway 98, east of Fairfield, that collects and conveys the stormwater through a ditch and pipe system and discharges to Jones Swamp. There are a few areas that have some minor flooding conditions during the 100-year critical storm event. The majority of these areas are located in the woods to the west of Fairfield Drive. There is also an area that the model shows some flooding of a business along Highway 98 just west of Fairfield Apartments during the 25-year critical storm event. This flooding is caused by the business being constructed in an area that is too low. The conveyance downstream of this area cannot be increased without causing flooding in the subdivisions downstream.

Branch D:

The primary drainage system in this Branch is a storm sewer system on Barrancas Avenue that extends from Old Corry Field Road to Fleet Road. Barrancas Avenue is a state road and the storm sewer was designed by FDOT using the FDOT standard, 3-year storm event. Using this criteria, the majority of the system is adequate for draining the roadway. However, there is one branch of the system that is flooding during the 3-year critical storm event, which is located on Jamison Drive. Other areas that the model shows significant flooding during the 25-year critical storm event are along Iona Street and Branywine Road. These areas are very flat and the stormwater cannot reach the existing storm sewer system. The other area that shows flooding during the 25-year critical storm event is the Pensacola County Club Golf Course. The golf course is the discharge location for the Barrancas Avenue Storm Sewer system. Other minor flooding conditions are located on Bayshore Drive and Harbourview Circle. The model shows these flooding conditions in the 100-year critical storm event.

Branch E:

The primary drainage system in Branch E is the remaining portion of the storm sewer on Barrancas Avenue. This portion of the system is located from Nimitz Court down to Old Bayou Chico Bridge and discharges directly to Bayou Chico. This portion of Barrancas Avenue is also a state road and was designed by FDOT using the FDOT standard, 3-year storm event. Using this criteria, the system is adequate for draining the roadway. These design standards match the results of the model. However, there are a few areas that show flooding during the 25-year critical storm event. These areas are located near Dixon Lane, Halsey Road, and Milton Road. Most of these areas show the storm sewer backing into the streets with a couple of instances backing into private and commercial property. The overall storm sewer is adequate for handling the drainage along Barrancas Street.

Branch F:

This area is located to the South of Navy Boulevard and North of Barrancas Avenue, east of Old Corry Field Road. Branch F is separated by Bayou Chico and was modeled as two separate systems. The systems in this Branch include storm sewers in Edgewater Drive and Chaseville Street, both of which are in the northern portion of the basin. Both systems are secondary systems

but were modeled to fully evaluate the problems in the Edgewater and Chaseville area. The remaining portion of this Branch does not have an existing storm sewer system in the northern or southern portions of the basin causing water to stand in the streets and yards. Additionally, flooding problems in this area were verified by field reconnaissance and questionnaires. The model shows majority of the major flooding conditions around Lakewood Drive and Rue Max Street during the 3-year critical storm event. Other areas such as Chaseville Street, Edgewater Drive, and Pelham Road show some flooding during the 25-year critical storm event. The storm sewer in this area is too small and does not cover all of the problem areas.

Branch G:

Branch G is located south of Mobile Highway and east of Citrus Street and bounded by the CSX railroad to the south. There is a storm sewer on Jackson Street that extends from Fitzgerald Street to Wiggins Street and outfalls to the ditch adjacent to the railroad. This system is a secondary system and is adequate for the area that it extends to. However, the remaining areas in the basin have no existing system, and the model shows some significant flooding in the other areas of Jackson Street during the 3-year critical storm event. In addition, there are some flooding conditions along Citrus Street during the 25-year critical storm event. The flooding in these areas are due to the lack of drainage systems causing the water to stand in streets and yards.

Branch H:

The primary drainage system for Branch H is the existing channel system associated to Jackson Creek. This channel system extends from Corry Field to the upper end of Bayou Chico. There is a secondary system on Corry Field that discharges into the Jackson Creek drainage system. Since this system is located on Federal Property and not within the County's right-of-way, no improvements are presented. The majority of the channel is adequate to collect and convey the stormwater up to the 100-year critical storm event. However, the model shows some major flooding in a couple of areas. One of these areas is located south of Idlewood Drive. This area is located in the Creeks flood plain so no improvements are proposed. The other area is along Old Corry Filed Road north of Jackson Street. There is a church, mobile home park, and several residences in this area that have severe flooding even during the 3-year storm event. This flooding is due to the lack of any

existing drainage systems.

Branch I:

The primary drainage system in Branch I is the storm sewer on New Warrington Road that extends from Navy Boulevard to Mobile Highway. New Warrington Road is a state road and the storm sewer was designed by FDOT using the FDOT design standards, 3-year storm event. Using these criteria, the system is more than adequate for draining the roadway. There are three secondary drainage systems also located in this basin. One system is located on Lillian Highway and another is located on Mobile Highway. Both of these systems discharge to the New Warrington Road system, and both roads are state roads. These systems were also designed using the FDOT 3-year storm design standard. The third system is located on Green Street that extends from Moreno Street to Mobile Highway, where it discharges. The model shows some minor flooding areas around the intersection of New Warrington Road and Lillian Highway. There are a few areas that show flooding in the 25-year and 3-year storm event. The majority of the areas that show flooding during the 25-year critical storm event are sporadically located along Mobile Highway and Lillian Highway. Most of these areas show the stormwater backing up onto private and commercial property due to low-lying areas on the east and west side of the road. The majority of the areas that show flooding during the 3-year critical storm event are areas that flood due to the lack of any existing storm sewer drainage facilities. The system on Green Street is significantly under sized and there are bowls in this area with no existing drainage systems. The model shows flooding conditions in this area during the 3-year storm event.

Branch J:

The primary drainage facility for this branch begins as a storm sewer system that extends along North 46th Avenue from State Street to West Jackson Street. From this point, the storm sewer discharges into a ditch system that extends to West Gregory Street and pops-off into the Jackson Creek channel. The model only shows one area with very minor flooding conditions during the 100-year critical storm event. Even though the model shows very limited flooding, questionnaires and field reconnaissance verify that some problems do exist, which appear to be associated with poor maintenance conditions of the existing system.

Branch K:

The primary drainage system for this branch is the upper end of the Jackson Creek channel, which discharges to the lower portion of Jackson Creek. This portion of Jackson Creek extends from Lillian Highway to Prieto Road where it discharges into the lower portion of Jackson Creek. The model for this portion of the systems shows no flooding conditions. However, the questionnaire verifies that problems do exist in this area. These flooding problems are in areas that lack existing drainage systems. This branch also contains a secondary storm sewer system that is located on North 57th Street from Annette Street to Lynwood Drive. The model shows flooding conditions in this area. The flooding conditions in this area are because the existing storm sewer system does not extend far enough to reach other low areas. In addition, there are numerous reports of flooding in other portions of this basin, though most of the reports are from areas that do not have existing storm sewer systems.

4.0 PROPOSED IMPROVEMENTS

4.1 OBJECTIVES & ALTERNATIVES

The development of a drainage improvement plan for the Warrington Basin as for all basins within Escambia County is conducted with the intent of meeting the following criteria:

(1) Eliminate roadway over-toppings at culvert/bridge crossings during the 100-year storm event for all primary arteries and evacuation routes.

(2) Eliminate roadway over-toppings at culvert/bridge crossings during the 25-year storm event for all secondary arteries and collectors.

(3) Contain the 25-year storm event within the banks of all open channels.

(4) Limit flooding during the 100-year storm event to streets and yards.

(5) Minimize street and yard flooding during the 25-year storm event.

(6) Provide for future growth/development in the basin where feasible.

(7) Reduce stormwater pollutant loadings to improve overall surface water quality standards.

Two different alternatives were explored to achieve these objectives. The first alternative is to increase the conveyance by up-sizing pipes and expanding channels. This method is the classic approach to solving stormwater flooding problems. However, increasing conveyance will yield relief at the point where improvements are made but it typically ends up moving problems to areas downstream. Another disadvantage to this method is that it does not address water quality improvements, making it extremely difficult to permit through the Florida Department of Environmental Protection (FDEP).

The second alternative is to increase storage in the upper reaches of the basin by constructing large retention/detention ponds to reduce the flows downstream. This method has become the industry standard in solving stormwater flooding problems. It provides a means to treat stormwater runoff as well as reduce flows downstream. These are the two main criteria FDEP reviews prior to issuing permits. The major disadvantage to this alternative is that it requires acquisition of large amounts of land, which can be a serious problem in built-out areas where vacant land is not available.

The approach used is a combination of the two methods. Retention/detention facilities will be used to treat and attenuate the runoff in all areas where there is vacant and/or obtainable land in practical locations. Conveyance will be increased in all areas deemed necessary to alleviate the remaining flooding problems without causing or exacerbating any downstream conditions. In built-out areas where there is no vacant and/or obtainable land for retention/detention facilities, roadside swales and underground treatment methods such as exfiltration trenches and treatment vaults (i.e. Stormceptors®) will be used to treat the runoff. This approach should satisfy FDEP's stormwater permitting requirements.

4.2 PROPOSED DRAINAGE IMPROVEMENTS

The improvements presented here are conceptual solutions offered to achieve the necessary objectives. Different alternatives were evaluated and those deemed the most feasible were selected. Because budget constraints may not permit funding of improvements for the entire basin, problem areas have been addressed by branch. This approach affords the county the opportunity to choose projects that will fit within the budget without having to implement the entire basin at once.

Branch A does not require any drainage improvements. There are a variety of drainage problems in Branch B. The major problem with the basin is that Lake Charlene is taking on too much stormwater. The first approach to solve these flooding problems is to determine which of the systems discharging to Lake Charlene can be re-designed and move outfalls to other locations. With this, some specific areas in the Lake Charlene drainage system have been identified that can be improved to help relieve and eliminate most of the flooding problems in this area. In addition to these proposed improvements, installing new systems to areas that have no existing drainage system will also help with the flooding problems in the area. In Branch C, most of the flooding problems are either flood plain related or not within the county's right-or-way. However, there is one area that does not have an existing stormwater system in place. The improvements in this area will be to construct a new stormwater system in the area of Saint James Place and discharge to the existing wetlands in the area. The proposed improvements in Branch D can be solved with a fairly straightforward approach. The primary branch of this system will not require any modifications.

One of the secondary branches of this system will need to have a few minor improvements, but the other secondary portion of this system will undergo a major modification and extension. Instead of this portion of the system discharging to the Barrancas system, this system will be turned around and extended to other areas that do not have an existing system. The new outfall for this system will be to Bayou Chico. Branch E: as stated earlier, this system was originally designed by FDOT using their standard of a 3-yr design storm; as a result certain areas flood during any storm equivalent to the 25-yr event and greater. Flooding problems in this area could be solved in several ways. If the proposed improvements, as suggested below in Branch F for the Lakewood Sub were constructed, then the overall basin draining to Barrancas Ave. would be reduced and flooding during the 25-yr storm would be eliminated. However the improvements to the Lakewood Sub are costly and also require significant land acquisitions. Other solutions that could be applied directly to Barrancas Ave would be to either redesign the storm sewer system to accommodate the 25-yr storm or provide an additional outfall to Pensacola Bay. As stated earlier, the Barrancas Ave system was designed to accommodate the 3-yr storm. Totally redesigning and reconstructing the system would eliminate all flooding during the 25-yr storm event and possibly the 100-yr storm, if the county should so choose. A third and possibly the most reasonable solution would be to provide an additional outfall south to Pensacola Bay, under Bayshore Drive. There are several side roads leading south from Barrancas Ave. on which the county owns right-of-way. Any of theses streets around the mid point of the Barrancas Drainage system would be suitable for constructing an additional outfall. Two examples would be Broadmoor Lane to Seamarge Circle or S Cary's Lane to Bayshore Lane. The restriction to this third option would be easement acquisition for the location of the outfall. Any of these three solutions could eliminate flooding issues during the 25-yr storm event; however the third option should be the most cost effective. One of the several possible locations for the new Barrancas Ave outfall has been included in the proposed conditions model, summarized in Table 4-1 and illustrated in Figure 4-1. Branch F will require some improvement in both the upper and lower portions of the basin. For the upper portion of the basin, the proposed improvements to the existing secondary system will be to modify and extend the system to areas the do not currently have an existing system. In addition, an outfall structure will need to be installed in the small drainage ditch on Frisco Road. The proposed improvements for the lower portion of this basin include a fairly large system that will require acquisition of land for a new retention/detention

facility. The proposed improvements for Branch G are also a straightforward approach. This improvement includes adding a storm sewer system along Citrus Street. This proposed system on Citrus Street will extend out to areas that do not have an existing storm sewer system and will have a pop-off to the ditch just north of the CSX railroad. The proposed improvement for Branch H is also a straightforward approach. This improvement includes adding a storm sewer system along Old Corry Field Road. The system on Old Corry Field will extend out to areas that do not have an existing storm sewer system and will pop-off to Jackson Creek. There are two areas in Branch I that have proposed improvements. One of the areas is in West Highlands, which does not have an existing storm sewer system. This proposed system will also require land acquisition for a new retention/detention pond. The other system is proposed for the Pen Haven Street area. This system is currently under construction as a County improvement project. Branch J does not require any improvements. All of the flooding in this area appears to be maintenance related. It is recommended that the county monitor this area for maintenance issues. Branch K has several areas of improvements proposed. One of these areas is located in the Emory Drive area. The proposed improvements on Emory Drive are to install a new system and construct a new retention/detention pond. A new system is also proposed for the Roosevelt Subdivision Area. In addition to constructing a new stormwater system, a retention/detention facility is also proposed. Land acquisitions will also be necessary for this proposed improvement. Another new system is being proposed for the area around Eaton Road. This system will only require the construction of the new stormwater system. The proposed pop-off for this system is to an existing stormwater pond south of Eaton Road. The fourth proposed system is the area of 49th Avenue at Lillian Highway. This improvement will be to construct a new system around the 49th Avenue area and discharge to the existing county stormwater pond on Lillian Highway. Figure 4-1 shows the proposed drainage improvements.

Lake Charlene / Querido Heights - Branch B:

There are several areas within this basin that need to be addressed. The biggest concern in this area is the amount of stormwater that is being diverted to Lake Charlene. Currently, Lake Charlene is at full capacity and cannot take on any additional stormwater without causing extensive flooding in and around the Lake Charlene Subdivision. It has recently been discovered that the County is

proposing and/or has completed several new projects in the area of Lake Charlene. Several of these systems are design to discharge directly or indirectly to Lake Charlene. The county systems that are in place are in the Myrtle Grove Drainage Improvements Projects. This project is broken up into seven systems. Of these seven systems, four of them will impact Lake Charlene. System B and parts of the Jackson Street system will directly discharge to Lake Charlene and System C, D and E will discharge to the pond on Myrtle Hill Circle which pops-off to Lake Charlene. Of these four systems, all of systems B, C and D have been completed with the exception of the interconnecting pipe that will link System D to System C. It is recommended that the County not proceed with any more of these projects that transport more runoff to Lake Charlene. Even though these systems have been mostly completed, there are several drainage improvements proposed in this study that will virtually eliminate the drainage problems in and around Lake Charlene. There are several separate areas that can be modified or re-design to achieve these improvements. One of the first improvements that need to occur is the modification to the Lake Charlene dam and outfall. This improvement will require that a large overflow structure be constructed at the south end of the Lake Charlene channel. This overflow structure will help reduce the overall water level of Lake Charlene and the channel associated with the Lake. The overflow structure will also help control the flow rate that is discharged into the outfall system. In addition to the overflow structure, the outfall system will need to be up-sized in order to get the necessary amount of water out of Lake Charlene to aid in the reduction of the flooding conditions. Another proposed improvement is to increase the size of the weir at the Lake Charlene Dam. The next proposed improvement is to take the discharge pipe on North 69th Avenue out of service. Taking this pipe out of service and re-designing the system on North 69th Avenue will reduce the amount of stormwater discharging into Lake Charlene. A new discharge location is proposed for the North 69th Avenue drainage system, which is to pop-off into the wetlands off of Campbellton Lane. Other areas of improvements involve up-sizing the storm sewer systems on 61st Avenue, Kittyhawk Drive, Lake Charlene Lane, and Myrtle Hill Circle. In addition to up-sizing the system on Myrtle Hill Circle, the discharge pipe from this system to Lake Charlene needs to be taken out of service and a new discharge constructed and connected to the proposed 69th Avenue system.

Should the above mentioned improvements to Lake Charlene be constructed excess capacity would be created in Lake Charlene. This would allow additional improvements to be made in Lago Vista Court. In particular an outfall for the three ponds in the Lago Vista development could be constructed, as shown in Fig 4-1 "Lago Vista Ponds".

Saint James Place - Branch C:

Most of the flooding problems in this Branch are either in the 100-year flood plain or not within the county's right-or-way. However, there is one area that does not have and existing stormwater system in place. Currently, there is no existing stormwater system in the area Saint James Place. The proposed improvements in this area will be to construct a new stormwater system designed for the 25-year storm event on Saint James Place and Dowdy drive. This system will discharge to the existing wetlands in the area.

Iona Street / Bayshore Drive - Branch D:

This portion of the Barrancas Avenue system at Iona Street will require minimal improvements to alleviate the flooding in this area. The proposed improvements to this part of the system are to up-size the pipes on Iona Street and Bayshore Drive. The proposed improvements for the Iona Street system are design for the 3-year storm event since this is a FDOT Highway and the improvements for Bayshore Drive are designed for the 25-year storm event. This is a straightforward and cost effective approach to alleviating the flooding in these areas.

Barrancas Avenue – Branch E:

Several options exist for addressing the flooding on Barrancas Ave; however the most straight forward and cost effective solution would be to construct an additional outfall to Pensacola Bay. There are several locations that a new outfall could be constructed. One such location has been modeled in the proposed conditions model to illustrate the benefits of an additional outfall. The suggested location would be to tie into the Barrancas system at Broadmoor Lane, south to Bayshore Drive, east to Seamarge Circle and then south to Pensacola Bay. Easements would have to be acquired from the residences in order to construct the outfall. If easements could not be acquired at this location then moving the outfall over a street to the east or west would still serve the same

purpose.

Jamison Street - Branch F:

The other portion of the Barrancas Avenue system will require more extensive improvements. This portion of the Barrancas system is at capacity and cannot carry any additional stormwater. Due to this, the proposed improvements for this system are to take the portion of the system on Jamison Street that connects the Barrancas Avenue out of service and install a new system along Jamison Street/Rue Max Street and discharge directly to Bayou Chico. This system will branch out to the local areas that do not currently have an existing system. The proposed improvements for the new system are designed for the 25-year storm event. This is a straightforward and cost effective approach to alleviating the flooding in the area.

Edgewater Drive - Branch F:

Branch F is separated by Bayou Chico. The proposed improvement for the northern portion of the basin is to extend and up-size the existing system on Edgewater and Chaseville Streets. The current system does not have the capacity nor does it extend far enough to areas that have flooding problems. The upgrades to this system are designed for the 25-year storm event. Also in the northern portion of the basin, improvements are proposed for the drainage ditch on Frisco Road and the Outfall pipe on eastern end of Edgewater Drive. The proposed improvement for the drainage ditch on Frisco road is to install an outfall structure in the drainage ditch and a discharge pipe directly out to Bayou Chico. The proposed improvement on the eastern end of Edgewater is to up-size the discharge pipe that currently extends out to Bayou Chico.

Lakewood / Millwood Terrace - Branch F:

The proposed improvements for the southern portion of the basin are to construct a new drainage system on Lakewood Road that will extend to most of the surrounding area. This new system will require the construction of a new retention/detention facility on Lakewood Road. The proposed location for the pond is on Lakewood Road across from Audusson Avenue. This property will need to be acquired in order to construct the new facility. An outfall system will also need to be constructed and is proposed to extend from the pond site across Lakewood Drive and out to Bayou

Chico. A drainage easement will be required to construct this outfall. In addition, a new secondary system is proposed for the northern area of Lakewood Drive. This system will extend down Lakewood Drive and connect to the existing discharge structure.

Citrus Street - Branch G:

The proposed improvements in Branch G include adding a new storm sewer system along Citrus Street. This proposed system on Citrus Street is designed for the 25-year storm event and will extend from Anthony Street down to Jackson Street and discharge to the ditch just north of the CSX railroad. In addition, this system will extend out to areas that do not have an existing stormwater system. A large regional stormwater pond will be required on this area to make the system work, therefore requiring land acquisition.

Old Corry Field Road - Branch H:

The proposed improvement for Branch H is also a straightforward approach. This improvement includes adding a storm sewer system along Old Corry Field Road. The proposed system extends from Border Street down to Jackson Creek, where it will discharge into Jackson Creek. This system will extend out to areas that do not have an existing storm sewer system. This proposed system is designed for the 25-year storm event.

West Highlands - Branch I:

There are two areas in Branch I that have improvements proposed. One of these areas is in West Highlands, which does not have an existing stormwater system. The proposed improvements for this area will be to construct a new stormwater system designed for the 25-year storm event. The new system will be located on Kirk Street and extend from West Avery Street to West Gonzalez Street and will extend to most of the surrounding area. This new system will also require the construction of a new retention/detention pond. The proposed pond site is at the corner of Kirk and Moreno Street. This pond site will need to be acquired in order to construct the pond. The proposed pop-off for this system will be to the Mobile Highway system.

Pen Haven - Branch I:

The other proposed improvement for this basin is a new system for the Pen Haven Street area. This system is currently under construction as a County improvement project and should solve the flooding problems in this area.

Emory Drive - Branch K:

There are several areas in Branch K where improvements are proposed. The first area is located in area of Emory Drive. The proposed improvements on Emory Drive are to install a new system along Emory Drive and extend it to Stanford, Stetson, and Vanderbilt Roads. This system will require a new retention/detention pond to be constructed. The proposed site for this pond is located at the eastern end of Tulip Drive. This property appears to be owned by Escambia County, so no land acquisition will be required. These proposed improvements are designed for the 25-year storm event.

Roosevelt - Branch K:

The second area that improvements are proposed is located in the Roosevelt Subdivision area. These improvements include a new storm sewer system along North 61st Street and will extend to 59th, 60th, 63rd, and 65th Streets. This new system will require the construction of a new retention/detention pond located just west of 61st Street. In order to construct the pond, land will need to be acquired. These proposed improvements are designed for the 25-year storm event.

Eaton Road - Branch K:

The third location for proposed improvements is the area around Eaton Road. This system will run along Eaton Road and extend to Feldor and Adkinson Drive. This improvement will only consist of the construction of the new stormwater system. The proposed discharge location of this system will be to the existing county stormwater pond south of Eaton Road. These proposed improvements are designed for the 25-year storm event.

49th Avenue - Branch K:

The last of the improvements that is proposed for this basin is located in the area of 49th Avenue. The proposed improvement for this area is to construct a new stormwater system along 49th

Avenue. This system will extend to the surrounding areas around 49th Avenue and discharge into the existing drainage ditch between 50th Avenue and 52nd Avenue. These proposed improvements are designed for the 25-year storm event.

4.3 DRAINAGE IMPROVEMENT RESULTS

The fourteen proposed drainage improvement plans offer solutions that bring almost all the flooding problem areas in the Warrington basin to within acceptable level of service standards specified in the objectives. These results will offer solutions that will help eliminate flooding in streets and yards during the 25-year storm event and eliminate residential and commercial flooding during the 100-year storm event. The proposed improvements were designed using software programs such as Storm CAD for storm sewers and Mod-Route for ponds to take advantage of the built in design mechanisms within the software that ADICPR does not contain. The results of these two programs are in Appendix E. The only exception to the design storm events is for the proposed improvements that tie into FDOT storm sewers that are only designed for a 3-year storm. These systems will have a 3-year capacity rather than a 25-year capacity unless available land can be obtained for a pond. The *Lake Charlene / Querido Heights* improvements are upgrades and expansion to an inadequate existing system. The design of this system was done with ADICPR because of the numerous drainage components within Lake Charlene. Table 4-1 shows the ADICPR model results storm for the proposed improvements. *Iona Road / Bayshore Drive* up-sizes the existing system for the western portion of the Barrancas system. Because this system ties into an FDOT system designed to their standards of a 3-year storm event, it will only have a 3-year capacity. *Jamison Street* improvements will require implementing a new system in the area where currently there is only a very small insufficient system. This system will be spilt off from the existing Barrancas system. Software results show no flooding conditions during the 25-year storm for this project. The *Saint James Place* improvements propose a system to an area that currently has no existing system. Software results show no flooding conditions during the 25-year system. *Edgewater Drive* improvements are upgrades and expansion to an inadequate existing system. *Lakewood Drive / Millwood Terrace* is in the southern portion of Branch F and will implement a new system in the area where currently there is no existing system. Program results show no flooding conditions during the 25-year storm for these proposed improvements. *Citrus Street* and

Old Corry Field Road will implement new systems in the areas where currently there are no existing systems. The Citrus Street system will require the construct of a regional stormwater pond. Program results show no flooding conditions during the 25-year storm event for these proposed improvements. The *West Highlands* project will implement a new storm sewer system in the area where currently there are no existing systems. This system will require the construction of a new stormwater pond. The software for this system shows no flooding conditions during the 25-year storm event. Branch K will require the implementation of four new systems in the area where currently there are no existing systems. Two of these systems (*Emory Drive* and *Roosevelt*) will require the construction of new stormwater ponds and the other two systems (*Eaton Road* and *49th Avenue*) will discharge into existing county stormwater ponds. These systems show no flooding conditions during the 25-year storm based on program results.

5.0 WATER QUALITY ASSESSMENT

5.1 INTRODUCTION

Two previous studies reviewed were the 1993 NPDES Phase 1 MS4 Permit Application for Escambia County and the Escambia County Stormwater Master Plan Needs Assessment prepared in November 1994 both by HMM and CDM. These two studies provided relevant information to water quality conditions. This analysis updates the water quality efforts of these two studies for the Warrington Basin. Escambia County was issued the NPDES MS4 Permit in January 1999 and has been required to submit annual update reports. The First, Second, and Third Year Annual Reports to this permit prepared by HMM and CDM contain updated pollutant loading estimates. These reports, however, have combined several of the original 41 basins in Escambia County and the data is not very basin specific.

This analysis is simulated using the same modeling protocol as the NPDES MS4 Permit annual reports with a more basin specific assessment. A spreadsheet, included in Appendix D, was used to estimate the total annual loading of various pollutants for the basin based on land use categories. This spreadsheet provides a basis for planning-level evaluations of long-term basin pollution loads and the relative benefits of Best Management Practices (BMP's) to reduce these loads. The 12 pollutants simulated in the loading analysis are the same 12 pollutants required by the Environmental Protection Agency (EPA) for the NPDES MS4 Permits. These 12 pollutants are five-day biochemical oxygen demand (BOD_5), chemical oxygen demand (COD), total dissolved solids (TDS), total suspended solids (TSS), total Kjeldahl nitrogen (TKN), nitrite plus nitrate (NO_3+NO_2), dissolved phosphorus (DP), total phosphorus (TP), cadmium (Cd), copper (Cu), lead (Pb), zinc (Zn).

Since the proposed improvements for the Warrington Basin call for new stormwater management facilities to resolve flooding problems, there is a potential for water quality improvements as well. With the implementation of the proposed ponds, roadside swales, and underground treatment vaults additional removal of pollutants can be achieved in the basin. The additional pollution reduction will reduce annual pollutant loadings from the basin and improve the permit-ability of the proposed improvements.

5.2 HYDROLOGIC PARAMETERS

Annual rainfall data recorded at the Pensacola Regional Airport for the years 1949 through 2003 were obtained. Based on the data for this time period, the average annual rainfall was 62.15 inches. The rainfall data is summarized in Table 5-1 at the end of this chapter. The years with no data shown are years with incomplete records.

The water quality spreadsheet calculates annual runoff volumes for the pervious and impervious areas in each land use category by multiplying the average annual rainfall volume by a runoff coefficient. A runoff coefficient of 0.95 was used for the impervious surfaces and a runoff coefficient of 0.10 was used for the pervious surfaces. The composite runoff coefficient for each land use category is calculated by weighting the impervious and pervious coefficients with the percent of directly connected impervious area (DCIA) for each land use category.

The Northwest Florida Water Management District's (NWFWMD) Land Use / Cover Classification System (FLUCCS) map for 1995 was used to determine the land use categories for the basin. This map appears to be the most complete digital record of land use data for Escambia County. Figure 5-1 at the end of this chapter shows the land uses from this map within the Warrington Basin. To develop the water quality spreadsheet, the 90 plus FLUCCS land uses were grouped into 13 general categories as used in the water quality modeling in the NPDES MS4 Permit annual reports. Table 5-2 shows the 13-modeled categories compared to the FLUCCS land uses.

5.3 POLLUTION LOADING ANALYSIS

The water quality spreadsheet uses land use specific Event Mean Concentrations (EMC's) multiplied by the estimated runoff volumes to calculate the annual pollutant load from a specific land use. The loads for each land use are added together to yield the annual pollutant load for the basin. EMC's are flow-weighted average concentrations defined as the sum of the stormwater pollution loads divided by the runoff volume. EMC's are widely used as the primary statistic for evaluations of stormwater quality data and the stormwater pollutant-loading factor in analyses of pollutant loadings.

The EMC's used in this analysis are the same used in the NPDES MS4 Permit annual reports. The data used for the majority of the land use categories were obtained from the updated EMC database for the southeastern United States. Nationwide EMC's reported by the Federal Highway Administration (FHWA) and EPA's NURP program were used for major roadways. Table 5-3 summarizes the EMC's used in this analysis and also sums up the acreages and percent DCIA for each land use category. The annual runoff and pollutant loading estimates calculated by the water quality spreadsheet are summarized in Table 5-4.

5.4 BEST MANAGEMENT PRATICES (BMP's)

BMP pollution reductions are estimated by reducing the loading from a specific pollutant by a relative amount related to the removal efficiency of a particular BMP and the drainage area covered by that BMP. Currently, BMP's in the basin are extended dry retention/detention ponds, which will remain the same for the proposed BMP's. Retention/detention ponds and roadside swales have both been classified as dry retention/detention. Removal efficiencies for the individual pollutants vary with the different BMP's and these values are listed in Table 5-5. The removal efficiencies for the treatment vaults are rough averages taken from several different manufactures.

Existing BMP's have a drainage area of approximately 158.9 acres treated by dry retention/detention ponds and approximately 558.7 acres treated by wet detention ponds. The proposed BMP's will provide an additional 474 acres of treatment by dry retention/detention ponds. Table 5-5 summarizes the pollutant loading reductions for each of the existing and proposed BMP's.

Table 5-6 shows the pollutant loading estimates for the basin without existing BMP's, with existing BMP's and with proposed BMP's called for by the anticipated improvements. It can be seen that while there is variation from parameter to parameter, the existing BMP's reduce individual pollutants by a range of about 1.2 to 9.2 percent. The addition of the proposed improvements increases pollution removal so that the effective reduction ranges up to an additional 5.2 percent for individual pollutants. Sediment-related parameters are reduced by about 2.1 percent overall, nutrients by 0.9 percent and metals by 3.4 percent. By comparing the estimated pollutant loading

for the Warrington Basin with and without the proposed BMP's, it can be concluded that the anticipated improvements will improve overall water quality within the basin.

Note: Total Improvement is the change between the results with proposed BMPs and existing BMPs.

6.0 RECOMMENDATIONS

6.1 COST ESTIMATES

Preliminary cost estimates were prepared for the proposed improvements in each project. Table 6-1 at the end of this chapter summarizes the estimates. These estimates include the costs for land acquisition for pond sites, engineering, construction costs, and contingencies such as mobilization, traffic control, and existing utility relocations. Engineering and contingencies have been estimated as percentages of the total construction costs. Unit prices were taken from the latest edition of the Pricing Agreement. Land values were estimated by taking the appraised values from the current tax rolls of the Escambia County Property Appraiser's Office. These values were multiplied by a factor of 1.5 since appraisal values tend to be less than market prices. An average land value per acre was used for portions of parcels. By project, the total estimated costs are as follows:

Lake Charlene / Querido Heights - Branch B	$ 5,060,253
Lago Vista Court – Branch B	$ 151,914
Saint James Place - Branch C	$ 675,196
Iona Road / Bayshore Drive - Branch D	$ 178,536
Barrancas Avenue – Branch E	$ 365,686
Jamison Street - Branch F	$ 1,968,915
Edgewater Drive - Branch F	$ 1,175,776
Lakewood / Millwood Terrace - Branch F	$ 3,373,773
Citrus Street - Branch G	$ 2,156,353
Old Corry Field Road - Branch H	$ 1,590,252
West Highlands - Branch I	$ 2,686,125
Emory Drive - Branch K	$ 476,795
Roosevelt - Branch K	$ 3,374,652
Eaton Road - Branch K	$ 911,957
49th Avenue - Branch K	$ 1,233,257
Total Cost	**$ 25,013,754**

6.2 PRIORITY RANKING CRITERIA

To help quantify the proposed drainage improvements, a matrix was developed to rank the improvements. The matrix is based on eight categories with six of these categories given points ranging from 0 to 10. The other two categories, flooding conditions and cost versus benefit, are weighted from 0 to 20. The points from the eight categories are summed for each project to produce a total score. Table 6-2 shows the matrix and the points given to each of the proposed improvements. This matrix was used to prioritize the proposed improvements within the Warrington Basin. The following is an explanation of the categories and scoring used in the Priority Ranking Matrix:

Improves Flooding Conditions: This category deals with improving existing flooding problems. A score of 16 to 20 indicates eliminating the most severe flooding problems such as flooding inside of homes and or businesses and roadway flooding of primary arteries and evacuation routes. Reducing severe yard, street and parking lot flooding and roadway flooding of secondary arteries and collectors would score in the range of 11 to 15. Improving moderate yard, street and parking lot flooding scores 6 to 10 and minor drainage conditions such as shallow puddles that tend to stand for periods of time after a rainfall event scores 0 to 5.

Improves Water Quality: This category rates the reduction of pollutants in stormwater runoff from the basin. A score of 8 to 10 would specify a significant reduction in pollutant loadings from an area that had a direct discharge to a surface water body with known water quality problems. Good to moderate overall reductions in pollutant loadings indicates a score of 4 to 7 and low to no reductions scores 0 to 3.

Provides for Future Growth / Development: This category scores the improvements based on the capacity of future growth and development the improvement provides. An improvement that provides stormwater treatment and conveyance for the majority of undeveloped areas would score in the range of 8 to 10. Improvements that supply capacity for portions of the undeveloped areas score 4 to 7. A score of 0 to 3 indicates that the area is either completely built-out or the improvement only provides for minor increases in runoff numbers.

Construct-ability: This category ranks the improvements on the ease or difficulty of building the project. A project that can be built fairly easily using straightforward construction techniques employed by the majority of local contractors that bid County jobs would score 8 to 10. A project that is more difficult but can still be accomplished by some of the local contractors with the aid of some specialty subcontractors and techniques would score 4 to 7. A score of 0 to 3 would be an extremely difficult to construct project that very few or none of the local contractors could build and would require out of town specialist.

Permit-ability: This category refers to the ease or difficulty of obtaining the necessary permits from the various regulatory agencies required to construct the improvements. A score of 8 to 10 identifies a project that does not require any permits or requires only general permits that can be easily obtained. A project that scores 4 to 7 requires permits that are more difficult to obtain but should still be granted by the regulatory agencies. A project that requires permits that have a good chance of being denied by one or more of the regulatory agencies scores 0 to 3.

Impacts Environmentally Sensitive Areas: Wetlands, shoreline protection zones, aquatic preserves, outstanding Florida waters, threatened or endangered species habitats, fishery and marine habitats, floodplains, potable water wells, areas containing endangered or threatened plants or vegetation, and areas identified by the Florida Natural Areas Inventory (FNAI) are all classified as environmentally sensitive areas. Any project having a negative impact on these areas would score a zero. A project that provides positive effects or has no impacts at all on these areas scores a ten. The potential for negative impacts to these areas would be scored a range of 1 to 9 based on the probability with nine being the lowest and one the highest.

Dependent / Independent: If a proposed improvement is a stand-alone project and independent of any other projects, it receives a score of ten for this category. If a proposed improvement cannot be implemented until another project is constructed first, it is considered a dependent project and receives a zero for this category. Projects with portions of the project dependent on other project are scored 1 to 9 based on the percentage of the overall project that is dependent.

Cost Versus Benefit: This category takes several factors into consideration. The project is rated based on the number of residences and businesses that benefit from the improvements, the severity

of flooding these residencies and businesses are experiencing, the appraised values of the residencies and businesses, and the cost to implement the proposed improvements. A score of 16 to 20 indicates a good rate of benefit for the cost to construct the project. A moderate rate of benefit for the cost to construct the improvements would score in the range of 11 to15 and a low rate of benefit per cost would score 6 to 10. A score of 5 or less would indicate a project that cost more than the value of the residences and businesses that flood.

6.3 RECOMMENDED PLAN OF ACTION

Based on the total score of each proposed improvement, the projects are broken down into four priority classifications. A Class I priority would designate a project that has a total score in the range of 80 to 100. Class I priority projects should be placed on the County's Capital Improvement Projects (CIP) list as the most immediate projects to be implemented. A score in the range of 60 to 79 would indicate a Class II priority and this class of projects should be placed on the CIP list to be implemented just behind the Class I projects. A Class III priority would be a project that scores 40 to 59 and the Class III projects should be placed on the CIP list to be implemented with any remaining funds left over after all Class I and Class II projects are complete. Any project scoring less than 40 is considered a Class IV priority. This class of projects should be placed at the bottom of the CIP list. It would probably be more feasible and cost effective for the County to look into buying-out and abandoning the residencies and businesses with severe flooding problems in the Class IV areas rather than implementing the proposed improvements.

The proposed drainage improvement projects for the Warrington Basin are listed below in order of priority along with their total scores and their priority classification:

Priority	Project	Score	Class
1	Lake Charlene / Querido Heights - Branch B	71	II
2	Jamison Street - Branch F	67	II
3	Lakewood / Millwood Terrace - Branch F	67	II
4	Emory Drive - Branch K	67	II
5	Citrus Street - Branch G	66	II
6	Old Corry Field Road - Branch H	66	II

7	West Highlands - Branch I	65	II
8	Edgewater Drive - Branch F	64	II
9	Lago Vista Court – branch B	62	II
10	Roosevelt - Branch K	60	II
11	Barrancas Avenue – Branch E	59	III
12	Iona Road / Bayshore Drive - Branch D	56	III
13	Eaton Road - Branch K	52	III
14	49th Avenue - Branch K	51	III
15	Saint James Place - Branch C	45	III

Lake Charlene / Querido Heights scores the highest and rates a Class II priority. It should be placed at the top Class II priority projects. Jamison Street, Lakewood Drive, and Emory Drive all score second and also ranks as a Class II Priority. These should also be placed on the CIP list with the rest of the Class II projects. Citrus Street and Old Corry Field Road score third and are also rated a Class II Priority. These projects should be placed on the CIP list with the Class II priority projects. Roosevelt and Lago Vista Court are the last of the Class II projects. Barrancas Avenue ranks at the top of the Class III priorities, followed by Iona Road, Eaton Road, 49th Avenue and lastly Saint James Place. All of these projects should be placed on the CIP list with the rest of the Class III projects.

APPENDIX C

ESCAMBIA COUNTY, FLORIDA
WARRINGTON BASIN DRAINAGE STUDY
QUESTIONNAIRE

The following questionnaire has been prepared to identify and evaluate drainage, flooding and/or water quality problems within your area. Please fill it out as completely as possible. Your cooperation is greatly appreciated.

RESPONDENTS NAME (Optional): _____

PHONE NUMBER (Optional): _____

ADDRESS (Please include): _____

RETURN TO: CarlanKillam Consulting Group, Inc.
Attention: Marc D. Bonifay, P.E.
5111 N. 12th Avenue
Pensacola, Florida 32504

1. How many years have you lived or conducted business at the above address? _____

2. Have you ever experienced flooding at this location? Yes _____ No _____

3. What type(s) of flooding have you experienced? (Check and describe below.)

   (a) Severe yard flooding of extended duration: _____
   (b) Severe street flooding of extended duration: _____
   (c) Flooding of business or residence: _____
   (b) Other (please describe.): _____
   _____
   _____

4. What date(s) do you recall flooding occurring? If you cannot remember exact date(s), give approximate date(s). If you have no idea, leave blank._____
   _____
   _____

5. What type of storm causes flooding of your property? (Check and describe below.)

   (a) A short intense rain, such as a thunderstorm: _____
   (b) A long moderate rain: _____
   (c) A long heavy rain: _____
   (d) Other (please describe): _____
   _____
   _____

6. If your house or business experiences flooding, how often does it occur? (Circle appropriate answer.)

(a)	Once a month	(d)	Once every two years
(b)	Once every six months	(e)	Once every five years
(c)	Once a year	(f)	Less than once every five years

7. If your yard or parking lot experiences flooding, how often does it occur? (Circle appropriate answer.)

(a)	Once a month	(d)	Once every two years
(b)	Once every six months	(e)	Once every five years
(c)	Once a year	(f)	Less than once every five years

8. If your street experiences flooding, how often does it occur? (Circle appropriate answer.)

(a)	Once a month	(d)	Once every two years
(b)	Once every six months	(e)	Once every five years
(c)	Once a year	(f)	Less than once every five years

9. Please name the streets and describe the locations that flood in your area. _____
_____
_____

10. What do you feel is the cause or major contributing factor to the flooding in your area? (Please describe.) _____
_____
_____

11. Are you aware of any water quality problems associated with stormwater runoff in your area?
Yes _____ No _____

Describe: _____
_____

Possible source of pollution: _____
_____

12. Please provide any additional comments you wish relating to drainage, flooding and/or water quality in your area. _____
_____
_____
_____
_____

APPENDIX D

WARRINGTON BASIN
STORMWATER QUALITY MODEL

Enter Rainfall & Runoff Coefficients:

Average Annual Rainfall (R) = 62.15 in/yr

Pervious Area Runoff Coefficient (C_P) = 0.10
Impervious Area Runoff Coefficient (C_I) = 0.95

Enter EMCs, Areas & % DCIA:
